

Writeup and Teamwork Assessment

Team: Lizzie Consolino

Project Description

This project creates a client server connection where the server is on the RPI and the client is on a computer laptop. There is a flask web server that prints details. The client side types in keywords and categories, and the server side handles the input of a csv file to json objects. The server posts the corresponding object from the client's request that has the keyword and category. The flask web server is templated with html with a pink background, purple text, and a cartoon of a wardrobe.

Block Diagram

Project components, protocols, signal processing techniques, sensing.

Sensor is considered to be the CSV file and laptop keyboard. The sensor - CSV- information is organized into a list of objects. The keyboard input uses filtering signal processing on the list of objects to return one object. The server code specifies paths for http get requests from the client side. The different CSV manager and import files search through the objects applying the filtering and request the object to be found through http get requests.

Limitations

Working individually, I found time management, as well as collaboration to be difficult. Ideally, there would be a reduced workload by working with a partner, as well as more effective debugging. Working with a partner also would have made planning the project easier because there would have to be a plan to divide tasks. Without having a partner, I spent way too much time thinking about different things to make for the project, because I didn't have to immediately come up with a plan, divide the plan into separate tasks.
